### Abstract

An overview of homoeopathic system of medicine with preventive approach and information about vaccination as well as response towards vaccination.

**Keywords:** Vaccination and homeopathy, plague, fever, venereal disease

### Introduction

Vaccination and homeopathy are important and controversial topics in the world. Some homeopaths support vaccination, while others do not. But before we can decide, what is a vaccine?

### Definition

A vaccine is a substance prepared by the causative agent, products, or synthetic material of the disease, used to stimulate antibody production and protect against one or more diseases, and processed to make an antibiotic that does not produce bacteria.

It was first used by Edward Jenner in 1798 to treat and prevent smallpox.

In the vaccine, pathogenic bacteria are produced through a special process, releasing antibodies to fight the infection. B lymphocytes originating from the bone marrow synthesize antibodies to produce immunoglobulin that provide temporary protection against diseases (such as allergic diseases) called hormonal protection.

In the vaccine, pathogenic bacteria are produced through a special process, releasing antibodies to fight the infection. B lymphocytes originating from the bone marrow synthesize antibodies to produce immunoglobulin that provide temporary protection against diseases (such as allergic diseases) called hormonal protection.

On the other hand, T lymphocytes originating from the thymus are responsible for providing a more or less strong protection called cellular protection. Protection through smallpox vaccination is an example of such prevention. A third type of inherited immunity is called genetic immunity. It is temporary and should be supported by appropriate measures after birth. A good example of this is the smallpox vaccine, which children receive at six months if the vaccine gets in the mother's blood.

The system is the best in this field as it is equipped with laws and nodes. "The patient is treated strictly according to his genetic makeup, the obstacles he will face during pregnancy and childbirth, the conditions in which he lives, and the type of will. A person's constitution and after new exposure to competition he gets used to receiving adequate protection. Similar". Therefore, it is particularly suitable for the treatment of all diseases that are desired to be prevented. Allergies are just a special case. Although recurrence of allergies cannot be completely prevented in the first phase of treatment, the frequency of recurrence will be less surprising and if yes, treatment should be stopped at the appropriate time.

Homeopathic remedies do not directly kill bacteria or viruses, but the important thing is that they strengthen the energy and eliminate the areas of growth and development, making the body immune. It is best for today's vaccines that work against the growth of body cells and sometimes cause other diseases.

The small amount of medical advice in the medical literature usually consists of treating two or three of the occasional diseases caused by a type of malaria with fixed characteristics, such as autumn sickness, plague, fever, venereal disease and cloth worker's itch.,

Add to this the negative discovery that minor diseases can be prevented by vaccination.

If you are not or are not getting these disgusting miasms, but have been vaccinated against something like smallpox or the plague, then you can be sure that you don't have miasma where true homeopathy is still needed, otherwise it will. Always causes physical and mental discomfort - not suddenly, but gradually and unconsciously. The mysterious and inexplicable way in which Syphilis and Sycosis gradually spread their effects throughout the body is little known, because the slow process is overlooked by the best observers, and Law often does not understand the reach. The poor person thinks that the pain (pathology) that is gradually built into him is the natural, normal pain.

Concerning the psoriasis theory, here is Hahnemann's following statement regarding injections, On December 19, 1831, Dr. Schreeter of Lemberg: "But if that's not possible (and children are more likely to get this disease than human drugs), I would recommend vaccinating other children to prevent infection after puncture. Show a little red, immediately after eating I give sulphur 1-30 two days in a row and vaccinate your child from the diseases it produces. As far as I know, children do not get psoriasis under the influence of sulphur."

In the written letter, Dr. Schreeter said she found the right instructions and administered the vaccines to get the best results.
